Introduction

Intended Use

The *Borrelia burgdorferi* IgG ELISA Kit has been designed for the detection and the quantitative determination of specific IgG antibodies against *Borrelia burgdorferi* in serum and plasma. Further applications in other body fluids are possible and can be requested. Laboratory results can never be the only base of a medical report. The patient history and further tests have additionally to be taken into account.

Background

*Borrelia burgdorferi* belongs to the family of spirochetes, of which three types have been identified to be human pathogenic: *Borrelia burgdorferi* sensu stricto, *B. afzelii* and *B. garinii*. The endemic areas of *Borrelia* are in Central and Eastern Europe, as well as Russia, China and Japan. The illness is transferred via tick bites, in Europe mainly by *Ixodes ricinus*. In the endemic zones, like Southern Germany and Austria, up to 50 % of the ticks are infected.

In the clinical course, after an erythema migrans, e.g. with neuroborreliosis, which appears at the first stage, also chronic arthritis, encephalitis, meningitis, myositis and hepatitis are observed. Treatment is done via different antibiotics, e.g. doxycyclin, amoxicillin, cefuroxim and penicillin G. A specific immunization is possible with immunoprophylaxis either by a recombinant OspA or by a recombinant polyvalent OspC vaccine.

The laboratory diagnosis is performed by the detection of antibodies in blood and cerebrospinal fluid. Methods employed are: ELISA, immunofluorescence, hemagglutination or Western blot. Besides whole cell extracts, recently there are increasingly used purified or recombinant single proteins as antigens. This brings however generally a decrease in sensitivity. It could be shown that between the various test methods there appear significant differences in the interpretation, so that the most reliable method seems to be the follow-up of the titer development. Western blot serves as a confirmatory test, because electrophoretically separated single antigens can be evaluated in their reaction with specific serum antibodies.

The *Borrelia burgdorferi* IgG ELISA test kit contains besides a whole cell antigen extract of *Borrelia burgdorferi* sensu stricto, which cross-reacts with *Borrelia afzelii* and *Borrelia garinii*, an addition of pure OspC, which increases the specificity and sensitivity of the assay. If the test shows only a positive IgG result (IgM negative), the immunity of the patient can be concluded. As mentioned above, in the case of a clearly positive clinical finding, there should be performed a confirmation of the titer increase with the same assay. With a positive IgM at the same time, there is a strong suspicion of an active disease.

Principle of the Assay

The *Borrelia burgdorferi* IgG ELISA Kit is based on the principle of the enzyme immunoassay (EIA). *Borrelia burgdorferi* antigen is bound on the surface of the microwell strips. Diluted patient serum or ready-to-use
standards are pipetted into the wells of the microtiter plate. A binding between the IgG antibodies of the serum and the immobilized Borrelia burgdorferi antigen takes place. After a one hour incubation at room temperature, the plate is rinsed with diluted wash solution, in order to remove unbound material. Then ready-to-use anti-human-IgG peroxidase conjugate is added and incubated for 30 minutes. After a further washing step, the substrate (TMB) solution is pipetted and incubated for 20 minutes, inducing the development of a blue dye in the wells. The color development is terminated by the addition of a stop solution, which changes the color from blue to yellow. The resulting dye is measured spectrophotometrically at the wavelength of 450 nm. The concentration of IgG antibodies is directly proportional to the intensity of the color.
### General Information

**Materials Supplied**

Storage Instruction

Store kit components at 2-8°C and do not use after the expiry date on the box outer label. Before use, all components should be allowed to warm up to ambient temperature (18-25°C). After use, the plate should be resealed, the bottle caps replaced and tightened and the kit stored at 2-8 °C. After the first opening the kit should be used within 3 months, the diluted wash buffer can be kept for 4 weeks at 2-8°C.

Materials Required but Not Supplied

- 5 µL-, 100 µL- and 500 µL micro- and multichannel pipets
- Microtiter Plate Reader (450 nm)
- Microtiter Plate Washer
- Reagent tubes for the serum dilution
- Bidistilled water
- Re-usable black lid for covering

Precautions for Use

- Only for in-vitro use!
- Do not ingest or swallow! The usual laboratory safety precautions as well as the prohibition of eating, drinking and smoking in the lab have to be followed.
- All sera and plasma or buffers based upon, have been tested respective to HBsAg, HIV and HCV with recognized methods and were found negative. Nevertheless precautions like the use of latex gloves have to be taken.
- Serum and reagent spills have to be wiped off with a disinfecting solution (e.g. sodium hypochlorite, 5%) and have to be disposed of properly.
- All reagents have to be brought to room temperature (18 to 25°C) before performing the test.
- Before pipetting all reagents should be mixed thoroughly by gentle tilting or swinging. Vigorous shaking with formation of foam should be avoided.
- It is important to pipet with constant intervals, so that all the wells of the microtiter plate have the same conditions.
- When removing reagents out of the bottles, care has to be taken that the stoppers are not contaminated. Further a possible mix-up has to be avoided. The content of the bottles is usually sensitive to oxidation, so that they should be opened only for a short time.
- In order to avoid a carry-over or a cross-contamination, separate disposable pipet tips have to be used.
- No reagents from different kit lots have to be used, they should not be mixed among one another.
✓ All reagents have to be used within the expiry period.
✓ In accordance with a Good Laboratory Practice (GLP) or following ISO9001 all laboratory devices employed should be regularly checked regarding the accuracy and precision. This refers amongst others to microliter pipets and washing or reading (ELISA-Reader) instrumentation.
✓ The contact of certain reagents, above all the stopping solution and the substrate with skin, eye and mucosa has to be avoided, because possible irritations and acid burns could arise, and there exists a danger of intoxication.
Assay Protocol

Reagent Preparation

✓ Washing Solution: dilute before use 1+9 with distilled water. If during the cold storage crystals precipitate, the concentrate should be warmed up at 37°C for 15 minutes.
✓ Strict adherence to the protocol is advised for reliable performance. Any changes or modifications are the responsibility of the user.
✓ All reagents and samples must be brought to room temperature before use, but should not be left at this temperature longer than necessary.
✓ Standards and samples should be assayed in duplicates.
✓ A standard curve should be established with each assay.
✓ Return the unused microtiter strips to the plastic bag and store them dry at 2-8°C.

Sample Preparation

Principally serum or plasma (EDTA, heparin) can be used for the determination. Serum is separated from the blood, which is aseptically drawn by venipuncture, after clotting and centrifugation. The serum or plasma samples can be stored refrigerated (2-8°C) for up to 48 hours, for a longer storage they should be kept at -20°C. The samples should not be frozen and thawed repeatedly. Lipemic, hemolytic or bacterially contaminated samples can cause false positive or false negative results.

For the performance of the test the samples (not the standards) have to be diluted 1:101 with ready-to-use sample diluent (e.g. 5 µL serum + 500 µL sample diluent).

Assay Procedure

1. Prepare a sufficient amount of microtiter wells for the standards, controls and samples in duplicate as well as for a substrate blank.
2. Pipet 100 µL each of the diluted (1:101) samples and the ready-to-use standards and controls respectively into the wells. Leave one well empty for the substrate blank.
3. Cover plate with the re-usable plate cover and incubate at room temperature for 60 minutes.
4. Empty the wells of the plate (dump or aspirate) and add 300 µL of diluted washing solution. This procedure is repeated totally three times. Rests of the washing buffer are afterwards removed by gentle tapping of the microtiter plate on a tissue cloth.
5. Pipet 100 µL each of ready-to-use conjugate into the wells. Leave one well empty for the substrate blank.
6. Cover plate with the re-usable plate cover and incubate at room temperature for 30 minutes.
7. Empty the wells of the plate (dump or aspirate) and add 300 µL of diluted washing solution.
procedure is repeated totally three times. Rests of the washing buffer are afterwards removed by gentle tapping of the microtiter plate on a tissue cloth.

8. Pipet 100 µL each of the ready-to-use substrate into the wells. This time also the substrate blank is pipetted.

9. Cover plate with the re-usable plate cover and incubate at room temperature for 20 minutes.

10. To terminate the substrate reaction, pipet 100 µL each of the ready-to-use stop solution into the wells. Pipet also the substrate blank.

11. After thorough mixing and wiping the bottom of the plate, perform the reading of the absorption at 450 nm (optionally reference wavelength of 620 nm). The color is stable for at least 60 minutes.
Data Analysis

Calculation of Results

The obtained OD of the standards (y-axis, linear) are plotted against their concentration (x-axis, logarithmic) either on semi-logarithmic graph paper or using an automated method. A good fit is provided with cubic spline, 4 parameter logistics or Logit-Log.

For the calculation of the standard curve apply each signal of the standards (one obvious outlier of duplicates might be omitted and the more plausible single value might be used).

The concentration of the samples can be read from the standards curve.

The initial dilution has been taken into consideration when reading the results from the graph. Results of samples of higher predilution have to be multiplied with the dilution factor.

Samples showing concentrations above the highest standard have to be diluted as described in “Assay Procedure” and reassayed.

- **Typical Calibration Curve** (Example. Do not use for calibration!)

<table>
<thead>

The results themselves should not be the only reason for any therapeutical consequences. They have to be correlated to other clinical observations and diagnostic tests.
**Performance Characteristics**

- Intra-Assay-Precision: 
  4.8%

- Inter-Assay- Precision: 
  7.7%

- Inter-Lot-Precision: 
  2.8 - 10.6 %

- Analytical Sensitivity: 
  0.99 U/mL

- Recovery: 
  79 - 88 %

- Linearity: 
  77 - 126 %

- Cross-Reactivity: 
  No cross-reactivity to TBEV (FSME).

- Interferences: 
  No interferences to bilirubin up to 0.3 mg/mL, hemoglobin up to 8.0 mg/mL und triglycerides up to 5.0 mg/mL

- Clinical Specificity: 
  97%

- Clinical Sensitivity: 
  88%

- Expected Values
  - In an in-house study apparently healthy subjects showed the following results:
